**“rebound effect”**

# Conclusions

- The effect of improving unit irrigation efficiency on basin irrigation efficiency is highly dependent on the hydrological arrangement of the irrigation units
- In closed basins, water is conserved only by reducing evapotranspiration
- The improvement of irrigation efficiency may entail an increase of water consumption (“rebound effect”)
- There is the temptation of investing “water savings” into an expansion of irrigated area, increasing water consumption (“rebound effect”)
- [There are good reasons to improve on-farm irrigation efficiency]
